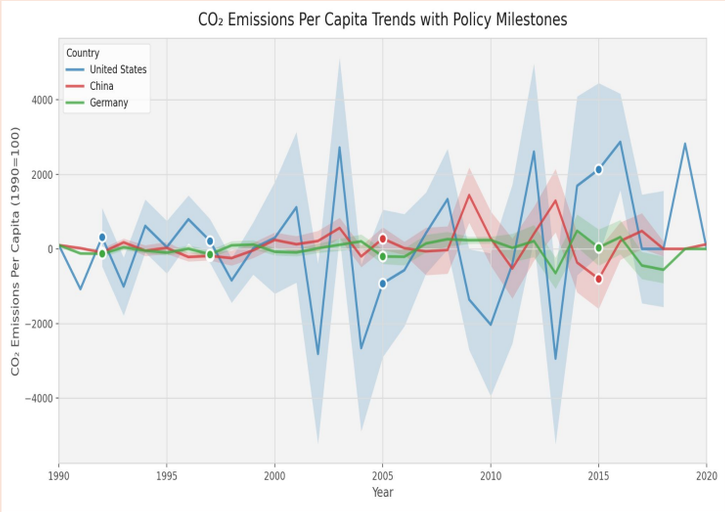
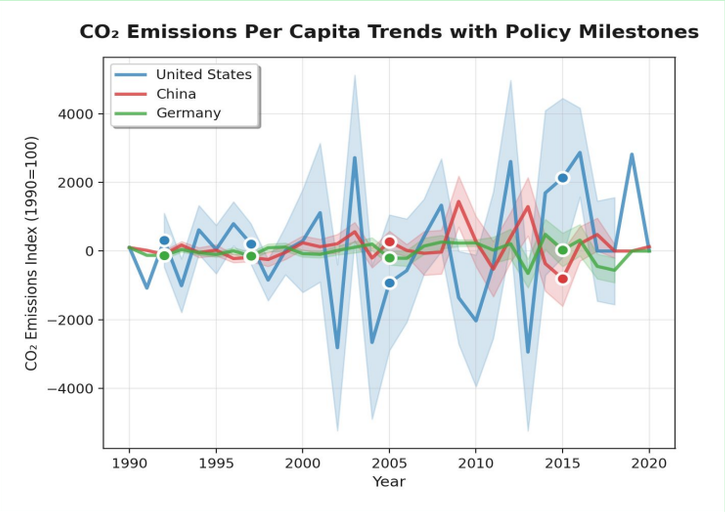
DV-Evol Good Case——python

Question:
- Convert CO_2 per-capita values to an index with 1990=100:
  idx(year) = 100 * value(year) / value(1990)
  Apply to line + rolling-std band + milestone points, and set y-label to include (1990=100).
- Enforce exact colors:
  US #1F77B4, China #D62728, Germany #2CA02C
  Keep alpha: line 0.8, band 0.2.
- Keep everything else unchanged:
  3-country layout, 1990–2020, milestones [1992,1997,2005,2015], marker style, title text, rolling window=5 (center=True).

GPT-5.2:



Ground Truth:



Successfully completed:
- Converted all series to an index normalized to 1990=100 (all three countries now show relative-to-1990 trends).
- Updated the y-axis labeling to reflect the index baseline, including "(1990=100)".
- Preserved and clearly separated the three country lines: United States / China / Germany.
- Applied the correct color mapping: US = blue, China = red, Germany = green (matching the gold chart).
- Added the rolling variability band (confidence-style / rolling std shaded area) with the expected translucent appearance.
- Plotted the policy milestone markers (highlighted year points with white edges).
- Kept the same time range (1990–2020) and maintained the overall structure: line + shaded band + milestone points.

Percentage Of Score: 71.875%
