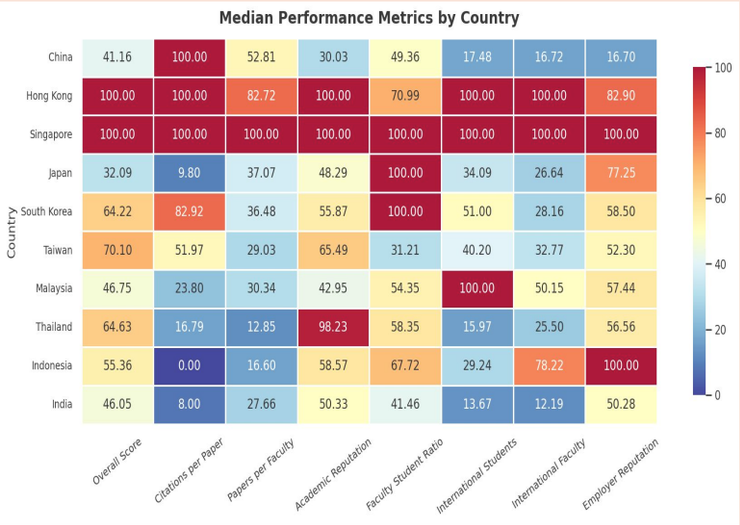
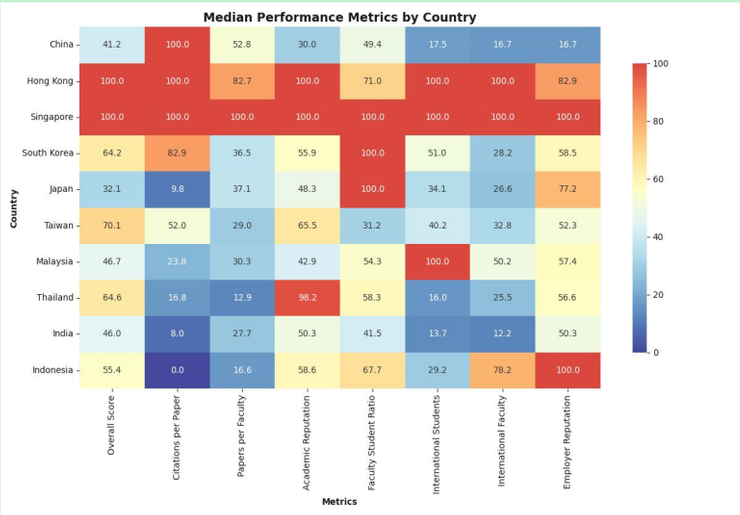
DV-Evol Good Case——vega-lite

Question:
- Change the aggregation from a correlation matrix to: median value of each metric per country.
- Build a heatmap with Countries on the Y-axis and the 8 numeric indicators (numeric_cols) on the X-axis.
- Update the title exactly to: "Median Performance Metrics by Country".
- Keep seaborn.heatmap, keep cmap='RdYlBu_r', and keep annot=True.
- Do not change the original asian_countries list or the numeric_cols order.
- Compute per-country medians for the 8 metrics (asian_countries) → heatmap (Y=Country, X=metrics), title = "Median Performance Metrics by Country", keep seaborn.heatmap + RdYlBu_r + annot=True, preserve country list + metric order.

GPT-5.2:



Ground Truth:



Successfully completed:
- Correctly switched from a correlation matrix to per-country median aggregation for each metric.
- Updated the title to exactly: "Median Performance Metrics by Country".
- Mapped dimensions correctly: Y-axis = countries (10 entries), X-axis = the 8 performance metrics.
- Kept the heatmap structure consistent (seaborn-style grid).
- Preserved numeric annotations inside each cell (annot=True).
- Included a proper colorbar and maintained the same high-to-low color trend as the reference.
